Starter Page

The problem

Monitoring CVA (credit valuation adjustment) by counterparty. The deliverable is a small dashboard: one filterable table of CVA charge per counterparty, backed by 20 mock rows (counterparty, CDS spread, tenor, CVA charge, timestamp). CDS spreads and CVA charges are static mock inputs, not computed — this is a monitoring UI, not a pricing engine.

The project is a vehicle to use one AI tool per SDLC stage and record why. It also exercises prior CVA domain experience (a full-stack CVA UI was previously built in React/C#). Target aesthetic: Bloomberg/AG Grid terminal density, not consumer SaaS.

The approach — one AI tool per SDLC stage

Stage	Tool	Result
Design	Stitch	Light and dark mockups; light variant chosen as the build target
Build	Replit Agent	One-page React app in 3 prompts; scaffold needed pruning
Component testing	Storybook	Empty / Populated / Error stories for `CvaGrid`; screenshots captured
E2E testing	Playwright	1 passing test: filter on "group" yields 4 rows, BNP Paribas absent
Review	CodeRabbit	Blocked — never reviewed the planted edge on PR #21; no review results claimed
Docs	Notion AI	This one-pager (in progress)

Each stage records why the tool was chosen and what actually happened, including failures: the dark-theme detour that contradicted the Module 1 decision, Storybook over-installing and needing to be pruned back, and a hand-counted test expectation (3 rows) that was wrong because "Citigroup" contains "group".

The stack

React + TypeScript, Vite, Tailwind, Storybook, Playwright. Data: `design/mock-data.json`. Runs locally with plain npm; no backend.

What I'd change next time

- Check each prompt against recorded decisions before running it.
- Prune or constrain tool defaults early — scaffolds and generators over-deliver.
- Verify third-party integrations on a throwaway PR first (the CodeRabbit install failed silently).
- Derive test expectations from the data, and prove tests can fail.
- Open the rendered output; a green build is not evidence.
